ACKNOWLEDGEMENTS

Firstly, a thank you to my supervisor, Shenuka de Sylva, for guiding me through this thesis; providing me with insight and encouragement to push my research.

Thank you to everyone who has helped me see my research through to the end, your support, encouragement and patience has been much appreciated.

Finally, I would like to thank to my parents, and family, your assistance and care throughout this year has allowed me to achieve to the best of my ability.
Quality atmospheric conditions and the ability to empower residents has been overlooked in recent social housing developments as they have been strongly economically focused. The demand for inner city social housing within New Zealand has been a pressing issue since the first worker’s dwellings were built in Petone.

Social housing residents are known for their comparatively low incomes and high needs, but this should not mean that they have to dwell in a different standard of housing from other income earners.

Social housing is a reality for a growing portion of our society in New Zealand; the location and quality of housing should not be defined by social stigma and hierarchy. Architecture as a discipline has unique potential to critique existing social housing standards and create diversity of atmosphere that evoke a sense of empowerment amongst residents.

This research explores the manipulation of hybrid prefabrication systems, with the aim of empowering social housing residents through diverse atmospheric conditions.

CHAPTER 1.0

Introduction
Over the last 30 years New Zealand has experienced a population growth larger than the world average, volatile immigration; an ageing population; cultural ethnic diversification; and a radical transformation of family structure. These factors all contribute to the increased demand for social housing (Housing affordability inquiry 82). The intensification of multi-unit dwellings in Wellington has been one of the most rapid in the country.

Recent decades have witnessed a prefabrication and social housing shift away from each other disregarding the ideals of home and becoming more economically focused. Social housing tenants have comparatively low incomes and high needs yet developers are coming up short of their expectations. A significant body of research now affirms that providing a home for these tenants that meets their needs is a powerful tool in constructing an individual’s identity and providing a sense of empowerment.

Despite this knowledge, social stigma’s associated with prefabrication and social housing inhibit innovative design opportunities that may provide a sense of home. “The inquiry has... identified that the current approach to social housing in New Zealand will not provide sufficient support for many New Zealanders in need” (Housing affordability inquiry 5). Zavei and Jusan argue that “ignoring human motivational factors in home making may lead to individual and social dissatisfaction” (319). It is through prefabricated social housing that this research investigates how architects can provide quality atmospheric conditions to empower tenants.

**Empowerment:** /ɪmˈpɔːrment/ n.

1. To enable;
2. Potential given to someone to do something

1.1

AIMS & OBJECTIVES

The primary aim of this thesis is to identify what constitutes higher quality social housing that would empower residents by enhancing relationships.

This can be achieved through:

1. Diversity of atmosphere, within and outside the home.

2. A sense of empowerment, while providing a sense of security and community.

3. The opportunities of hybrid prefabrication and how these techniques can enhance the atmospheric conditions.
1.2

RESEARCH SCOPE

This research focuses on the relationship between the built environment and the atmospheric conditions in social housing. Exploration includes the diverse atmospheric conditions needed to develop a sense of empowerment within the residents, and the opportunities of hybrid prefabrication methods.

This thesis explores how prefabrication can be utilised to provide quality construction with efficiencies that traditional construction cannot provide. The design solution for this research uses existing solutions to advocate universal design principles as best practice that can be used to establish a standard of the atmospheric conditions that can be achieved within this context of housing.
Figure 1.04. Nairn Street Council Flats outdoor space backs onto public walkway
1.3

METHODOLOGY

The process behind this thesis is reflected through research and design experimentation at a series of key stages; firstly, a personal interest in prefabrication drove the design research into exploring issues of atmospheric conditions and empowerment in architecture. Secondly through literature review, in order to set up a design framework, thirdly to analysis a number of case studies against this framework to understand the effective solutions and the drawbacks of current multi-unit housing developments. Each of these key stages of research is responded through iterative design experimentation using sketching, digital modelling, digital diagramming, planning, programming and computer rendering of representative imagery.

Figure 1.05 illustrates the research process; highlighting the importance of each research stage.

CHAPTER 2.0

Social Housing, Empowerment, & Atmosphere
NEW ZEALAND SOCIAL HOUSING
Background Analysis

1900

Government passed a new Workers’ Dwelling Act. Then withdraw it.

September 1937, Prime Minister opened the first state house in Miramar, Wellington.

1939 the first central city blocks, Centennial Flats, were established in Berhampore.

1923 saw new Californian bungalows spring up.

1920’s the state was financing nearly half of the houses being built.

Railways programme was initiated.

1940 plans to construct larger blocks in downtown Wellington and Auckland.

After 1944 the government began planning whole suburbs of state housing.
Figure 2.02. New Zealand Social Housing timeline showing the progression of social housing in New Zealand from 1900 - today.
2.2

WELLINGTON SOCIAL HOUSING
Statistical Analysis

In Wellington, the intensification of multi-unit dwellings has been one of the most rapid in the country, yet 51% of families living in New Zealand housing stock have reported major problems with their house or neighbourhood (Housing affordability inquiry 45-46).

The following statistics highlight the demand for social housing in Wellington City that is yet to be satisfied as recorded from the 2013 census data:

- **211** Families needing Social Housing in Wellington
- **159** 1 & 2 bedrooms required within Wellington City
- **143** Families in need of housing are rated Priority A

A suitable living environment is made possible by meeting users’ needs and preferences. It is necessary to investigate into the current social housing statistics to appreciate the relationship between architectural attributes and the users’ needs, to achieve a sense of home. Zavei and Jusan argue that the lack of attention to human motivations in housing originates from the diverse lifestyle and variety of needs (312). Today tenants are multi-cultural, with low-wage employment or no employment, and some physically and mentally affected re-established into the community; all relying on government support. It is important to design for the diverse needs of these tenants to be able to provide a sense of empowerment and an attachment to a community.

LITERATURE REVIEW

New Zealand culture

Prefabrication is a method of construction embedded into New Zealand culture. Since the beginning of New Zealand settlement prefabrication can be linked to influences from the pre-1800 Maori and early European settlers. The early 1900's saw prefabrication and social housing become intrinsically linked with high quality construction, materiality and a sense of home that was established throughout New Zealand.

Today, it is those very qualities that are sought after within a home and yet developers are coming up short of expectations. As of recent prefabrication and social housing seem to be growing further apart leading to the demise of the desire for this type of housing. The concept of social housing has evolved from the 1900's single detached dwelling to today's medium density developments. However, the issue of creating quality affordable houses, especially within urban areas continues to be a problem (Schrader 7). Throughout the history of social housing in New Zealand we see this type of housing become densely configured units and move away from its traditional construction technique of prefabrication.

Prefabrication stigma

“It is important to establish a strong awareness surrounding prefabrication if it is going to flourish within New Zealand. The public, the industry and the government must be educated to develop a positive outlook on prefabrication within New Zealand”.

(Bell)
Prefabrication is increasingly seeking to abolish the social stigma associated with such housing and one significant way this is being attempted is with no compromise in the quality of construction. It is our experiences with temporary prefabricated classrooms and mass-produced kitset homes which are responsible for the social stigma associated with this type of construction and have led to a negative overview of prefabrication in New Zealand (Bell and Southcombe 41). It is the inferior atmospheric conditions associated with social housing that stigmatises it and has inspired the body of this research; as architects how can we design to empower social housing tenants through quality atmospheric conditions?

As the industry is in the slow process to abolish this stigma, it is important that prefabrication can provide an opportunity to make architecture as accessible, affordable, and sustainable for a wide demographic of New Zealanders as well as meeting the requirements for improved standards in materiality and construction.

The role of prefabrication

There are challenges to abolishing the stigmas associated with prefabrication that would promote widespread application of these methods in New Zealand. No one method of prefabrication will solve the issues of the construction and housing industry. A collaborative approach of multiple systems is more likely to develop increased efficiencies needed in this industry.

High standards of construction and quality are being achieved in medium-high income brackets but these same standards are not applied to low-income housing. Traditional construction methods are increasingly viewed as cost efficient as the time into prefabricated systems are considered time consuming and unachievable. However, traditional construction methods can be slow, unpredictable and there is
more room for error. Architects Stephen Kieran and James Timberlake argue that the traditional construction methods are governed by one rule:

\[ Q \times T = S \times C \]  
(11)

These four factors are not amiss in prefabricated construction. Prefab can offer more for less, as shown in figure 2.05, to provide the quality of housing that satisfies the ideals of home.

Zumthor speaks in a poetic way about the collection of different materials in this world available to architects and designers to combine for creating better quality spaces (23). This notion alerts to “a way of bringing separate parts of the building together so that they formed their own attachments”, to enable an expressive nature. This is a concept that can be applied to prefabrication; a collaborative system of building materials and components, integrated beautifully, so spaces are not defined entirely by its construction methods but by the collaborative nature of the materials and the components they form (Zumthor 43). Utilising various prefabrication systems, while focused on a collaborative approach, beings to create a diverse materiality palatte, which in turn “react with one another ... so that the material composition gives rise to something unique” (Zumthor 25).

**Social housing stigma**

The stigma associated with social housing in New Zealand has developed a ‘stamp’ that we put on certain housing or neighbourhoods that is of a lower standard to those in its surroundings. Typically, these housing developments are pushed out of the cities and into the suburbs as inner city land is believed to be too valuable for such housing. Hobsonville Point, a new development in suburban Auckland, is an example of valuable land that was initially meant
psychological health and well-being. To avoid the negligence of humanistic values in housing and the related damages, the design of the environment must be properly linked to personal factors.

Fig. 1. The reasons behind inattention to human motivational factors and the consequences

3. Maslow's hierarchy of needs

Culture, as viewed by Maslow (1970), is a reflection of a person's motivations in response to the effects of external agents imposed from natural and built environment (Figure 2). According to Maslow (1970), satisfying the basic needs of a person is important for developing and actualizing potentialities and capacities of the person in society. His theory of human motivation explains people's different levels of needs without their superficial differences, using a concrete and tangible approach, and a specific classification. This theory focuses on the origins of human needs by highlighting a pervasive and universal definition of these motivations.

Fig. 2. External fields as a transition between motivations and behavior. Source: Maslow, (1970).

Motivations

</tbody>
</table>

Fig. 5. Theoretical model of personalization in built environment

Considering the above discussions about motivational factors, it is necessary to develop a concept representing the role of different levels of needs in provision of housing. This is because although the user's cultural values are the most significant determinants of their housing preferences, the most critical and fundamental stage is to specifically highlight the users' exclusive motivational level and the relation between architectural attributes and the user's needs. Once the motivational level and the relations were clarified, cultural interpretation leads to identifying a set of tangible and concrete architectural attributes to properly satisfy these motivations. Otherwise, the diversity of the motivational factors and the ambiguity of the relations with architectural attributes make it impossible to apply them properly. As a result, developing a theoretical framework to address the issue from a basic needs perspective is essential.

The theoretical framework should be able to explain how the different levels of needs filter the built environment and eventually suggests how architectural attributes i.e. fixed, semi-fixed, and non-fixed, and their physical dimension including their visual composition and appearance can be associated with the users' motivations.

Both models of evaluation discussed earlier are based on cultural elements which suggest systematic approaches to understanding users' motivational factors in relation to housing attributes. To the authors, it is possible to consider Maslow's hierarchy of needs as the origins of cultural elements as a filtering or evaluating agent. Therefore Jusan and Sulaiman (2005) model of personalization can be modified to suit the purpose of this study, in which the different levels of needs are shown in the model as evaluating agents. Other filtering elements indicated in the earlier models are considered as still relevant but are not shown in this model (Figure 5). Indeed, the user's needs are emphasized because it is believed that they are the origins of other motivations, and their definitions are more tangible and concrete, and include a specific classification.

Figure 2.06. The reasons behind inattention to human motivational factors and the consequences (Zavei and Jusan 313)

Figure 2.07. Theoretical model of personalisation in built environment (Zavei and Jusan 317)
to develop a mixed community of affordable and social housing. The social housing aspect of his development has since been removed to provide around 4,500 affordable houses for families and retirement living (Schrader 31).

Social housing is a reality for a growing portion of our society and their location and quality of housing should not be defined by social stigma and the economic hierarchy within our society. It is evident that atmospheric ideals can be achieved in higher income housing yet these standards are not being transferred to social housing. Theory indicates that “the major shortcomings of current houses remains their inability to fully satisfy the needs of residents” (Zavei and Jusan 312). Abolishing social stigmas associated with social housing is the beginning of providing housing that empowers residents.

**Empowerment**

The empowerment of occupants and the humanistic aspects of living in has gradually decreased as social housing has become an economically focused product (Zaver and Jusan 312). A framework for future social housing must provide a balanced approach between the four well-beings of community; economic, social, environmental and cultural. (Bierre et al. 70) Linking Maslow’s hierarchy of needs to the built environment, directs one to housing that has the potential to meets these criteria and supports a balanced approach to housing. Such an approach is influential in constructing an individual’s identity, evoking a sense of empowerment and strengthening their sense of responsibility to society (Zavei and Jusan 312), in other words happier and healthier tenants.

The architect has an imperative role in developing a sense of dignity for the occupants where “space becomes place” (Kennedy 43). Social housing tenants have comparatively lower incomes and higher needs, however standards and quality of housing...
should not differ from other income earners. Maslow’s theory on human motivation explains the different levels of needs without superficial differences by focusing on the origins of human needs and by highlighting a universal definition of the motivations that drive human beings, as seen in figure 2.06. With these personal factors linked to the environmental conditions, personal motivation and empowerment of the occupants is achievable (Zavei and Jusan 313).

Atmospheres

It is accentuated in various literature that atmospheres are “perpetually forming and deforming, appearing and disappearing, as bodies enter into relation with one another. They are never finished, static or at rest” (Anderson 79). Literature from Wigley, Anderson and Böhme begin to describe atmosphere as something that is ‘indeterminate’ and ‘intangible’ surrounding buildings, clinging to material objects and emanating from objects and form as “some kind of sensuous emission of sound, light, heat, smell and moisture” (Wigley 18).

For Zumthor, it is an attentiveness to the atmosphere and mood that is an inevitable responsibility of the designer. Spaces can be described as “a ‘ritual place,’ ... a ‘system of symbols,’ a communicator of ideas” (Kennedy 43). Home is to offer a haven for its occupants while being able to communicate with viewers, residents, visitors as well as the immediate neighbourhood (Zumthor 7). Various literature has led to the identification of these generators as figure 2.10 identifies and shows the cyclical affect that they have on each other.
Figure 2.10. The four key aspects that are the atmospheric generators important for social housing and the cyclical affect each aspect has on each other.
Figure 2.11. Regent Park was a new build that was a part of the Wellington City Council Housing Upgrade Project.
Conclusions

This research has established:

a) the opportunities quality prefabricated systems offer social housing and for achieving modern medium density spatial ideals through better atmospheric conditions;

b) Social housing in New Zealand is economically driven and not meeting the atmospheric desires of its residents, leading to a lack of empowerment across this demographic;

c) atmospheric generators that empower residents and the community can be identified to define the positive atmospheric qualities desired for social housing.

This literature reviews the undeveloped potential for architectural research to explore diversity of atmosphere within social housing, providing an opportunity to empower and improve the lives of social housing tenants.
Figure 3.01. Regent Park occupation 4 years after completion.
CHAPTER 3.0
Case Studies
3.1

INTRODUCTION

Four different medium density housing precedents were researched to inform the design research:

1. Triangle Road
2. Te Aro Pā papakāinga
3. Regent Park
4. Zavos Corner

Critical reflection on these examples is an opportunity to identify potential design objectives concerning social housing, prefabrication, a sense of empowerment and atmospheric quality; for example, natural light, space planning, individualisation and architectural identity.

Design Framework

Focusing a wide range of ideas from literature reviews to those which are most relevant to this research has produced the following criteria. These criteria will serve as a framework to guide the design research the research objectives and review each case study.

Each criterion selected is seen to provide humanistic aspects to a living environment, and contribute towards a sense of empowerment. This framework provides a set of goals to drive the design development process, as well as creating a test to measure the success of design outcomes.
Figure 3.02. Design framework to evaluate the selected case studies, showing a selected segment

Figure 3.04. Living interior of a Triangle Road dwelling.

Figure 3.05. The homogenous exterior of Triangle Road dwellings.
3.2

TRIANGLE ROAD,
Strachan Group Architects

Architect: Strachan Group Architects
Location: Triangle Road, Auckland
Size: 2,200 m²
No. Dwellings: 10
Density: 45 dwellings per hectare
3.2.1 What is the project?

Triangle Road is a Community Housing project for VisionWest Community Trust who offer community based services to some of West Auckland’s most vulnerable residents. This project was designed to satisfy a number of objectives around construction methodology as well as offering an alternative approach to medium density housing in Auckland (“Triangle Road Community Housing” Community; sec. 1).

3.2.2 What are the atmospheric qualities?

Community: The community objectives of Triangle Road were “to provide greater opportunity for social interaction, passive surveillance and a greater sense of community” (Vision West Community Trust 1). This has been a successful aspect of the development that brings the occupants closer together while creating a community atmosphere that evokes a sense of pride. Each dwelling has a stepped façade entry that creates a focal entry point to each dwelling, however the materiality has a homogeneous aesthetic creating a row of housing that looks identical.

Exterior: The external atmospheric qualities of Triangle Road are not as successful at their interiors. The materiality and homogeneity of these dwellings develops a repetition that has no variation other than the depth of the façade. This alternating façade depth begins to relieve the eye as well as creating recessed individual entries for the dwellings. The aesthetics and materiality of the exterior don’t provide a significant architectural identity; this could have been accentuated more through materiality, as well as height or form variations.

Interior: The interior atmospheric qualities of these dwellings offer much to be desired for prefabricated social housing in New Zealand. The interior treatment of the dwellings has helped to show that
Figure 3.06. Site and floor plan analysis of Triangle Road
Atmosphere can be achieved within social housing and that construction systems have the ability to aid the aesthetics instead of controlling them. A successful sense of depth and spatial quality have been designed with the exposure of the primary structure, a warm material palate and light, bright open spaces. These dwellings have a compact footprint on their site but have been able to create light spaces to a high quality.

3.2.3 What are the construction techniques?

Triangle Road uses prefabrication methods to aid in their objectives around construction speed, innovation, and thermal performance. The primary structure of these dwellings are comprised of concrete floors, precast concrete inter-tenancy walks, prefabricated mid-floor panels of cross-laminated timber (CLT) and structurally insulated panel (SIP) roofing.

Triangle Road has been rather innovative by bringing multiple prefabricated systems together within these dwellings. Using multiple systems to complete one build is the next step into developing a more efficient building methodology for prefabricated social housing.

3.2.4 Summary

This project offers a “precedent in the on-going affordability vs. quality discussion” and is a great beginning for the desired atmospheric qualities desired in prefabricated social housing Auckland (“Triangle Road Community Housing” Community; sec. 1). The community and interior atmospheric qualities exceed the ideals needed to create a positive atmospheric conditions.
Figure 3.07. Triangle Road fulfilling eight of the ten criteria, lacking in architectural identity and exterior atmosphere.
Figure 3.08. Interior living qualities within a dwelling of Te Aro Pā

Figure 3.09. Exterior atmospheric qualities of Te Aro Pā
3.3

TE ARO PĀ PAPAKĀINGA,
Walker Architecture & Design

Architect: Roger Walker, Walker Architecture & Design
Location: Great Point, Wellington
Size: 2,048 m²
No. Dwellings: 14
Density: 68 dwellings per hectare
3.3.1 What is the project?

Te Aro Pā is Wellington’s first city papakāinga which is privately owned by the Te Aro Pā Trust. This housing development has been designed as social housing for the people who have a connection to the original Ngāti Ruanui and Taranaki Iwi. (“Te Aro Pā papakāinga – the power of partnership.” News; sec 1) Roger Walker has shifted from his distinctive architectural style and has developed Te Aro Pā around the traditional Māori concept of whanaungatanga, kinship.

3.3.2 What are the atmospheric qualities?

**Community:** Due to the location, the row housing formation of this development begins to hinder the community atmospheric conditions possible for Te Aro Pā. Although private and shared space has been made available within the development for social interaction there is a significant lack of privacy within these spaces. Te Aro Pā has been backed up against a hill, without being blended into the existing community surroundings and has been left to stand out without changing the public perceptions of social housing.

**Exterior:** The exterior atmospheric qualities of Te Aro Pā provide an architectural identity which is not typical of Roger Walker. While this is not of Walkers usual aesthetic Te Aro Pā still stands out with stepped façade heights, materiality and irregular glazing proportions that create whimsical approach to traditional Maori concepts. This case study has shown that exterior atmospheric conditions are not complete without the surrounding being taken into consideration. It is crucial that an architectural identity is developed in response to its surrounding context to create a greater sense of community and dignity for its occupants, especially when dealing with a specific demographic for social housing.

**Interior:** The contemporary spaces have a cold
Figure 3.10. Site and Floor plan analysis of Te Aro Pā
neutral colour palate and the atmospheric qualities have been compromised by the exposed structural walls and the irregular glazing proportions. The glazing proportions limit the amount of daylighting resulting in a large impact on the interior atmospheric qualities of these dwellings. Te Aro Pā has reinforced the importance of solar gain within dwellings to improve the interior atmospheric qualities. Natural light levels have a significant impact on the atmospheric conditions and it is important to maximise the benefits of this when possible.

3.3.3 What are the construction techniques?

The primary construction of Te Aro Pā are the structural pre-cast concrete walls. These walls act as shear walls for the building as well as inter-tenancy walls between dwellings. Using this method of prefabrication this housing development was able to be constructed in less than six months.

This example of prefabrication within a new contemporary development shows how the structure can begin to dominate and affect the space. Although the shear walls allow for maximum space allotment within the building footprint, the decision to expose this materiality has had a significant effect on how the space is interpreted.

3.3.4 Summary

Overall, the Te Aro Pā has achieved something for Ngāti Ruanui and Taranaki Iwi people that has never been accomplished before, however, has it has failed to change the stigma of social housing. Te Aro Pā has been isolated in Greta Point without developing a relationship with the existing community surroundings. This case study has been significantly beneficial as it has helped to identify the new and existing issues with social housing.
Figure 3.11. Te Aro Pā fulfilling six of the ten criteria, lacking in individualisation, social engagement, interior atmosphere as well as visual connections.
Figure 3.12. Regent Park exterior atmospheric qualities

Figure 3.13. Regent Park interior atmospheric qualities
3.4

REGENT PARK,
Design Group Stapleton Elliott

Architect: Design Group Stapleton Elliott
Location: Newtown, Wellington
Size: 6,447 m²
No. Dwellings: 27
Density: 42 dwellings per hectare
3.4.1 What is the project?

Regent Park is a low income medium density social housing development undertaken by the Wellington City Council as part of an upgrade to their housing portfolio. Regent Park previously contained social housing that was not fit for purpose and architects, Design Group Stapleton Elliott, were responsible for the redevelopment. The development contains a range of various housing typologies that respond to a difficult site.

3.4.2 What are the atmospheric qualities?

Community: The biggest success of Regent Park is the public and private outdoor space. The built forms within this development have been pushed to the edges to allow for a self-enclosing public space that has passive surveillance from the transparent circulation towers and each dwelling in the complex. This provides the occupants with a sense of safety and community and is a huge asset for a social housing.

Exterior: The building forms and materiality have a contemporary architectural twist on traditional 19th century villas as a response to the site surroundings. This gives Regent Park an architectural identity within the wider community and a sense of belonging for its occupants. The extensive colour palate has been used as a colour code for the buildings which impairs on the atmospheric conditions as this is not typical of higher income housing developments. It is the colour coding that begins to define the development as a low-income social housing and continue the identity of social housing.

Interior: The interior atmospheric conditions within Regent Park are less than desirable due to the low quality finished and materiality. How these dwellings are fitted out have a huge impact on how we perceive the quality of a space, this is where a prefabricated
Figure 3.14. Site and floor plan analysis of Regent Park
bathroom/kitchen pod would be able to set a high quality standard throughout and increase the atmospheric qualities.

3.4.3 What are the construction techniques?

Regent Park was a development for the Wellington City Council using traditional construction methods. It is more common to use traditional methods in new council developments as it is increasingly viewed as a more reliable method of construction.

3.4.4 Summary

Regent Park’s interior and exterior atmospheric qualities are an example of how atmosphere can be improved within social housing. The Regent development has some promising factors that have been put in place to provide the occupants with positive atmospheric qualities. However, there are still some significant disadvantages within this project such as its construction techniques, material quality, form and compact room sizes that make it a case study of great learning value.
Figure 3.15. Regent Park fulfilling five of the ten criteria, lacking in half the identified conditions to design for social housing in New Zealand
Figure 3.16. Interior atmospheric qualities of a dwelling in Zavos Corner

Figure 3.17. External aesthetics and atmospheric qualities of Zavos Corner
3.5

ZAVOS CORNER,
Parsonson Architects

**Architect:** Parsonson Architects  
**Location:** Mount Victoria, Wellington  
**Size:** 564 m²  
**No. Dwellings:** 8  
**Density:** 142 dwellings per hectare
3.5.1 What is the project?

Zavos Corner is a private medium density housing development in Mount Victoria. The development consists of one two-level apartment and seven single-level apartments that have been spread over 3 stories. The eight apartments range from one to three bedrooms where each dwelling has a different floor plan (Hansen 139).

3.5.2 What are the atmospheric qualities?

Community: There is a great sense of community within Zavos as it has been designed as a space enclosing structure around a north facing courtyard with private and public areas. The height of these dwellings provide passive surveillance from the small decks at each end of the living spaces. The high level of thoughtful design has developed a strong sense of community within the development as well as fitting in with the greater neighbourhood.

Exterior: The exterior form of the building has been developed to read as a village than a housing complex to create a connection with the surrounding building and community within Mount Victoria (“Zavos Corner 2015” Housing; par 1). These apartments give a vertical presence on the street front, where they look like individual townhouses or apartments but are actually two interweaving single-floor dwellings (Hansen 144). This has become an aesthetical interest of the development, creating a whimsical architectural identity for Zavos Corner.

Interior: The interior has been planned to make sure that the spaces “felt open and generous but with privacy between dwellings” (Hansen 144). The building has been arranged around a north facing central area that connects each apartment, resulting in private living and outdoor spaces that are filled with light and various surrounding views.
Figure 3.18. Site and Floor Plan analysis of Zavos Corner
3.5.3 What are the construction techniques?

Zavos Corner has used traditional construction methods consisting of light timber framing that has been clad in corrugated iron and plastered concrete panels (“Zavos Corner 2015” Housing; par 1).

This development is already of a high quality and has challenged opinions and thoughts on medium density housing in Wellington, however it would have been one step further to utilise innovative methods of construction.

3.5.4 Summary

Overall, Zavos Corner has produced an incredibly high standard of exterior and interior atmospheric qualities. It is the careful planning and individualisation of the interior and exterior that has provided the occupants with a sense of ownership and identity within this development.

The interior atmospheric qualities have been developed with a high quality material finish, as well as the large sense of space. Developing a light space that has the ability to capture various light qualities and surrounding views has developed a sophisticated sense of space that has the ability to be directed into social housing developments.

3.6

CASE STUDIES
Conclusions

These case studies offer a lot of positive atmospheric qualities, previously identified within the literature review. The comparison chart (figure 3.21) defines some important factors for consideration in design and when focusing on creating quality of space through atmosphere. Figure 3.21 summaries these case studies and shows a brief overview of what is currently working within these housing typologies and what each example is lacking.

Community: These case studies have proved that a sense of community within a development is evoked through the massing on the site and how the dwellings begin to respond to each other. It is apparent that space enclosing structure(s) develops a greater sense of community than that of a linear block of dwellings. This has aided how to approach the massing studies of the dwellings on site and highlighted the importance of social interaction and passive surveillance to prompt a greater sense of community.

Exterior: The exterior analysis of these case studies has showed that a cohesive material palate in combination with form and pattern variations develop a high aesthetical interest as well as a sense of identity for the architectural style and occupants. It is important to provide the occupants with the ideals of home to evoke a sense of pride and aspects as small as individual entries to the dwellings and application of personalisation allow this.

Interior: The interior atmospheric conditions
of these case studies have shown the importance of light and solar gain within a space. Natural light qualities have the potential to completely transform how a space is perceived. A development that has made the most of glazing proportions, site orientation and solar gain has shown to have the desired interior atmospheric qualities.

Some of these case studies provide the beginning of collaborative innovation where high quality spaces and construction methodologies are being brought together in harmony to develop an aesthetically interesting and powerful atmospheric space. While others have provided an understanding of what is missing in our current social housing standards. With a bit more consideration, architectural space can become not only accessible but negotiable, and encourage choice, as well as transformation through personal initiative (Kennedy 44).

CHAPTER 4.0

Contextual Studies
4.1

URBAN ANALYSIS

Central Wellington has been selected for its proximity to all the cultural, social, educational and recreational amenity offered by the city centre. Social housing tenants have comparatively low incomes and high needs so it is important that this location can offer diverse amenities to satisfy a wide range of tenants. This location offers a unique set of conditions and challenges to work with when testing the research objectives.

This urban analysis aims to establish a site for further investigation and design development. Three exemplar social housing sites have been selected for initial analysis of their suitability to enable a challenging design investigation. McLean Flats, Pukehinau Flats, and Arlington Apartments are all located in Wellington and are in need of redevelopment to provide a quality atmospheric conditions that evoke a sense of empowerment within its occupants.
McLean Flats

The McLean Flats located on The Terrace, housing 14 one bedroom flats was built in 1944 and influenced by the ‘international style’ of modernism. These flats were evacuated in 2011 as the building was deemed earthquake prone and unsafe for human habitation.

Constructed on the smallest site, 1,492m², it is by far the most challenging of sites for a housing development. The steep topography, limited daylighting and proximity to amenity provide a unique set of conditions and challenges.

Pukehinan Flats

The Pukehinan Flats have a site area of 6,990m² and are located at the bottom of the Brooklyn Hill. This site has had alterations and additions since the initial flats were built, however there has been no further developments to improve the atmospheric conditions of the site.

These flats are in close proximity to amenities, yet the site conditions do not provide the complexity and challenges needed for this research project.

Arlington Council Flats

The Arlington apartments were designed by Ian Athfield in 1970’s and made up of various townhouses as well as an apartment block of dwellings.

These apartments are currently under redevelopment and have been split into two phases due to the size of the complex. This site is the has the biggest area of 14,310m², which sets a challenging task.
Figure 4.03. McLean Flats evacuated in 2011

Figure 4.04. Pukeshinau Flats still occupied

Figure 4.05. Arlington Apartments still occupied
Figure 4.06. Figureground urban breakdown surrounding the three selected sites
Separating distinct elements of the urban structure surrounding the three sites facilitates a clearer analysis of what contributes to the sense of place of each area; building use, green amenity, and transportation networks.

The McLean Flats site is selected for further investigation and design development. This site offers a range of challenging conditions such as topography, limited solar gain, and site area. McLean Flats is a central city location and will provide diverse challenges to test and develop this research.
Figure 4.08. Diagram analysing existing site conditions

Figure 4.09. Initial massing diagram responding to site conditions
To gain an understanding of the site in its existing condition, these diagrams aid in the initial condition testing. These diagrams provide a rough idea of the site surroundings and begin the initial programming to be able to design for the occupants' needs and generate a development that can provide the ideals of home, and a sense of community.

**Figure 4.10.** A diagrammatic massing formation responding to site conditions
The design process begins with a series of initial site analysis and diagramming (Chapter 4). From these studies emerge two massing iterations which investigate solutions for prefabrication, density, light, privacy (Chapter 5). These ideas are then refined and presented as a design solution for the site (Chapter 6). Finally, reflection identifies strengths and weaknesses of the design outcome, and proposes further solutions for developing a model able to be implement in other sites (Chapter 7).

Consideration Framework

The design framework established in the precedent studies is referred to throughout the design development phases, both as a set of goals driving design decisions, and as a measure of testing the success of the design outcomes.

It is this consideration framework that has been broken into four predominant design considerations; atmospheric, socio-economic, cultural and prefabrication. All of these conditions rely on each other to produce a successful design solution for this research. It is important that these considerations are referred back to throughout the development phases in accordance with the design framework.
Figure 4.11. Design consideration table showing the linear and cyclical nature of how these conditions rely on each other to produce a successful design solution.
Figure 5.01. Pukehinu Flats from Nairn Street
CHAPTER 5.0

Design Processes
This stage is focused on a design-led exploration of ideas. Two concept schemes are evolved in a series of iteration experiments with dwelling developments, in order to resolve:

a. accessibility;
b. light; and
c. privacy

These also served as an investigation into important architectural qualities such as programme, planning, aesthetics, prefabrication methods and functionality.

**Design Framework**

The design framework established in chapter 3 is used as a guideline for design decisions, and to measure the success of the design outcome.

Ten criteria were identified from this framework as they are seen to provide humanistic aspects of a living environment that contribute towards a sense of empowerment.

These criteria are tested through the design process and reviewed to measure if the design outcomes are meeting the design challenges; to provide tenants with a sense of identity and empowerment thereby conveying a sense integration with the wider community.
Figure 5.02. Design framework established in chapter 3 to inform the design process
5.1 HYBRID PREFABRICATION

Introduction

As our current demand for housing goes up, previous trends seem to show that these increases have consequences on the quality. It has been made apparent through various attempts and challenges that a singular approach to prefabrication is not going to solve our housing issues and especially our social housing sector. It is through a hybrid approach to prefabrication that the efficiencies needed in social housing and the positive atmospheric conditions, that evoke a sense of dignity amongst tenants, can be achieved efficiently and more successfully.

Hybrid prefabrication is a term typically used for a combination of systems such as a volumetric and panel approach. These systems use volumetric units for highly utilised areas such as the kitchen and bathroom while the rest of the house is constructed with a panel system. A hybrid approach to prefabrication combines the benefits of multiple systems, allowing increased efficiencies and flexibility (Bell 37). For this reason, hybrid prefabrication has a future within the current demand for social housing in New Zealand.

There are various volumetric and panelised methods within New Zealand with Xlam CLT, Metrapanel and UniPod being the most favoured hybrid methods of construction. These panel systems have been brought together in various projects successfully. The UniPod combines both of these panel systems into a pod, this has immensely improved efficiencies and qualities in kitchens and bathrooms. These mixed systems have been utilised to create a hybrid prefabricated system, that is both efficient and innovative, and as they provide opportunity for better atmospheric standards within social housing.
5.1.1

XLam CLT

+ Large Span Values
  Structural Properties
  Accuracy
  Aesthetic Value
  Atmospheric Properties

- Associated Costs
  Acoustic Performance
  Fire Retardant Properties
  Volume of Material

Cross-Laminated Timber (CLT) is a solid wood panel that is made from layers of timber laminated together in alternating directions. This engineered timber provides structural properties with life cycle savings that make this system ideal for structural use within social housing.

Having moments of this system exposed within the interior of the dwelling offers a warm aesthetic to the space. Using quality materials in construction enables higher standard of housing and living, and is the first step to abolishing the stigmas of prefabrication and social housing.
5.1.2

METRAPANEL

+ Changability
  High Thermal Properties
  High Tolerance
  Easy Assembly
  Cost Efficiency

- Limited Sizing
  Architectural Development
  Exterior System

The Metrapanel system consists of engineered 36mm walls to create the interior surface of a building. Using this system construction can be increased by 40-60%. To use this system in the context of social housing, a variation of panels would be required to produce high quality standards.

The Metrapanel system allows for the flexibility needed if this was to be used for future social housing developments. This system does not attempt to control and define the atmosphere of its interior space, instead aid the methods to develop a positive atmospheric space for its occupants.

High - Low Spec Variation
- Needs development

Vertical Stacking

The UniPod is a volumetric unit that has so far only been prototyped. It is the hybrid volumetric unit of XLam CLT and Metrapanel. It is made up of double skinned Metrawall framed with CLT for stability. The double skinned wall contains a cavity for all the services and acts as the core of the building.

The UniPod encapsulates the essential kitchen and bathroom spaces back to back, however, as this system is only a prototype there is still of room for improvement.

The UniPod was initially selected as part a key component to this hybrid prefabricated system as the core of each building. It was thought that this system would provide a high standard of quality which in turn is the initial steps to developing positive atmospheric condition in the key areas of a home.
5.1.4

HYBRID PREFABRICATION
Conclusions

Figure 5.10 shows the potential collaboration of these three systems and how they would begin to benefit each other. The CLT for structural purposes, Metrapanel as the interior wall system and the UniPod as an efficient service pod that brings the highly utilised areas of the house onto two walls.

These systems channel innovation, efficiency and the opportunities for development of a hybrid prefabrication system that could set the standard for prefabricated social housing. Applying this system on a challenging site enables testing the opportunities it presents and the possibilities for its adaptation to other sites around New Zealand. These systems combined offers quality, flexibility and a standard that can be set as an achievable bar for better social housing.

Figure 5.11. System Axonometric with Metrapanel and CLT Detailing
5.2

MASSING STUDIES

Massing studies were used to explore and visualise potential volumes and thresholds. These are the conceptual beginnings of the design phase, and start investigating the atmospheric opportunities created within the exterior and interior of a social housing complex and its engagement with the wider community environment.

Test Iterations

Digital modelling and drawings were used to explore preliminary responses to the existing site conditions. These explorations were informed by the criteria identified in the design framework (Chapter 3), such as creating diverse atmospheric conditions, visual connections, an architectural identity and to evoke a sense of empowerment.

Note that the criterion “prefabrication” has been proposed in the initial stages of chapter 5. The remaining criteria have been reviewed throughout the design process.

These massing studies have been developed in response to a combination of dwelling types ranging from two to three bedrooms and to provide for the needs of a wider scope of people and future changes.
Figure 5.13. Design framework established in chapter 3 to inform the design process; prefabrication methods established
5.2.1: SCHEME 1

Figure 5.14. Scheme 1: Vertical stack diagram & example section
Figure 5.15. Scheme 1: Solar studies of the massed form on site during the Summer and Winter solstice
Visual Connections

The programme is designed as a vertical stacking model and terraced using the natural contours of the site to provide visual connections at various levels of the site. Currently the shared space is made up of little pockets throughout the site, however there is still opportunities for further development using a larger central space.

Exterior Atmosphere

This design aims to increase densification from the current conditions but in doing so has produced an undesirable exterior atmosphere within the pockets of shared space.

Social Engagement

The height and density of this scheme does not provide a high level of social engagement throughout the site. The small pockets of shared space and vertical formation may provide some social engagement through the site but this won’t enable the levels of engagement this thesis aims for.
Figure 5.16. Scheme 1: Site plan massing with suggested unipod placement; scale 1:

PRIMARY SHARED OUTDOOR SPACE

SITE VEHICLE ACCESS
Figure 5.18. Scheme 1: Shared outdoor space/terraced units section
Scheme 1 Summary

A particular challenge for the vertical circulation model is balancing heights without creating dark central spaces on the site. The solar analysis and shade diagrams is evidence that the height and density of the buildings blocked the light through most of the day in the summer and winter solstice, creating rather unpleasant environments and experiences for tenants.

Vertical stacking decreases the inter-tenancy acoustic issues, however due to the extreme site conditions it is evident that a vertical approach to massing does not provide all the dwellings with the opportunity to enjoy desired and diverse atmospheric conditions. Decreasing height and density of the dwellings would have a significant impact on the atmospheric conditions of the development.

The challenges of this initial design resulted in the development of the following scheme with focus on balancing competing requirements for access, lights and privacy.
5.2.2: SCHEME 2

Figure 5.19. Scheme 2: Vertical stack diagram & example section
Figure 5.20. Scheme 2: Solar studies of the massed form on site during the Summer and Winter solstice
Social Engagement

Scheme 2 has been developed so that the various dwelling typologies begin to rely on each other and create inter-occupancy moments through circulation and shared public spaces. This allows for the density of the site to be increased while spreading the buildings to the edges of the site and creating a central public domain.

Community Atmosphere

This scheme has been strongly influenced by the advantages laid out in the case studies and has focused on developing a strong sense of community. The massing formation provides a central public space with two additional rooftop spaces for entertainment and community gardens.

Interior Atmosphere

The solar analysis, figure 5.20, has shown that the form and height of buildings need careful consideration to ensure each dwelling captures natural lighting throughout various times of the day. Capturing lighting qualities through the day enhance the interior spatial atmosphere and enables better living environments.
Figure 5.21. Scheme 2: Site plan massing with suggested unipod placement; scale 1:1.

ROOFTOP FOR ENTERTAINMENT, COMMUNITY GARDENS AND PROVIDING PASSIVE SURVEILLANCE OVER PUBLIC SPACE

PRIMARY SHARED OUTDOOR SPACE

TERRACED SPACE FOR VEHICLE ACCESS
Figure 5.23. Scheme 2: Shared outdoor space/terrace units section
Scheme 2: Summary

This scheme developed as an opposing idea to scheme 1. The focus was to create a flow between public and private with centralised atrium circulation acting as threshold spaces. With more development and using various techniques such as levelling, materiality, permeability and planting a balance of public and private can be achieved.

The horizontal nature of this scheme makes it a concept that is more versatile and transferable to other sites around New Zealand. If this scheme can be developed to create the desired atmospheric conditions and evoke a sense a dignity amongst its tenants, it is possible to take this framework and adapt it for social housing developments on other sites.
Figure 5.24. Initial sketch ideas of dwelling development for Scheme 2
Figure 5.25. Design framework that has been established through the current design phases.
5.3

UNIPOD CONFIGURATION

Iterations Studies

The next stage is a design-led exploration to establish desired interior atmospheric qualities. These iterations evolved from the initial sketch ideas to understand how prefabrication could be incorporated into space planning. Starting investigations into prefabrication systems early in the design phase developed an in-depth understanding of these systems and enabled an innovative architectural outcome that is not limited by construction methods.

This investigative study served as an important learning curve as difficulties arose when trying to plan for the services running through the UniPod. The UniPod is a prototype that has not yet been utilised in a built space. While the UniPod would be ideal for a ‘cookie cutter’ housing scheme stacked one on top of the other, which is not the aim of this research project, a more versatile system needs to be developed.

The UniPod lacks flexibility of use in a home environment particularly where the bathroom is to be the main one in the house, and certain facilities need to be usable and accessible at all times. For example, the washing machine, bathroom and kitchen. At the moment these separate features of the UniPod could not all be utilised at once, and for a three bedroom dwelling, this becomes a significant design limitation.

5.4

SERVICEBOX
Developmental Process

Due to the limitations with the UniPod, a unit more adaptable and flexible was needed. This resulted in the development of the ‘Servicebox’. It has been design for greater efficiency and flexibility of use. In addition, the design of the Servicebox, offers more living space and provides opportunities that the Unipod could not.

The next stage investigates the issues surrounding the UniPod and shows the evolution of the Servicebox.

Figure 5.30. Servicebox exploded axonometric
5.4.1

SERVICEBOX
The Problem

The UniPod system is designed to combine the necessary functional requirements of a home into a smart wall that encompasses the services and provides the amenity of a bathroom and kitchen. The UniPod provided a glimpse into the future of medium-density housing, however when put into a two storey house plan, issues began to arise.

Figure 5.32 shows the limitations associated with the UniPod prototype, the dominant being restricted floor plan arrangements. These limited arrangements began to dictate the architectural features of the house and control the atmospheric qualities and limits what’s achievable.

This thesis focuses on achieving low-cost housing that delivers an architectural identity through diverse atmospheric qualities. The UniPod prototype was a prefabricated system that did not fulfil the objectives of this research. These issues drove the design of the Servicebox, a system that provided efficiency and flexibility to achieve the objectives of this research.

Figure 5.31. Servicebox delivery and installation process
LACK OF KITCHEN BENCH SPACE
LACK OF BATHROOM STORAGE
FUNCTIONS CAN'T BE USED INDIVIDUALLY
MINIMAL SPACE REQUIREMENTS
WATER CYLINDER STORAGE
CROWDED SERVICE WALL
LIMITED STACKING OPTIONS

Figure 5.32. UniPod limitations
5.4.2

SERVICEBOX
The Solution

The Servicebox aided in the development of atmospheric qualities within the dwellings. It provided more efficiencies with flexibility and individualisation as shown in figure 5.33.

This exploded axonometric illustrates the benefits of the Servicebox as well as the increased flexibility, additional workspace and storage has been incorporated. The addition of an electric water heater instead of a storage water cylinder provided increased efficiencies with storage and reduced the overall weight of the unit.

The biggest advantage of the Servicebox is that all of its functions (kitchen, bathroom and laundry) can be all used independently and simultaneously. The interior atmospheric advantages achieved with the Servicebox are far superior and is a prefabricated unit that can be used to meet the needs of social housing tenants.

Figure 5.36. Servicebox Bathroom
Figure 5.37. Servicebox Kitchen adaptability and individualisation
Figure 5.38. Servicebox Kitchen
5.5

DWELLING DEVELOPMENT
Iteration Studies

The development of the Servicebox created more flexibility and architectural control when designing. The next stage was a design-led exploration to achieve a dwelling arrangement that achieved desired interior atmospheric qualities. These iterations evolved from the initial UniPod iteration studies, however these iterations had more space planning options.

This investigative study served as an insightful step into producing dwellings for atmosphere. Designing these dwellings with 3D computer modelling, it was possible to simulate light qualities that were achievable in each space.

This process was then executed with the three alternative dwelling typologies to achieve a space arrangement for each that was unique and fulfilled the requirements of the interior atmosphere criterion outlined in the design framework.
Figure 5.39. Dwelling development iteration studies; dwelling 1

Figure 5.40. Dwelling development iteration studies; dwelling 2
5.6

FORMAL STUDIES

Consideration of formal architectural qualities begins with objectives drawn from initial case studies that should respond to and sit in harmony with its surroundings.

The surrounding buildings on the project site located on The Terrace follow a diverse aesthetic of architecture. However, the majority of houses on The Terrace are notable for their villa characteristics. The physical characteristics of the villa include timber weatherboard cladding, a welcoming street frontage, and the iconic pitch roof shape. These characteristics can also be linked to initial social housing from 1900’s, the prefabricated railway houses. Figure 5.42 shows the four roof types available from these railway houses.

Examples of contemporary architecture were investigated for further inspiration. Key elements include clean lines, simple and durable materiality, and a strong visual axis through the interior out to the landscape. The overall effect is of a modern twist on the traditional railway pitched roof houses.

5.7

DESIGN PROCESS
Evaluation

Scheme 2 has been driven by the ten criteria in the design framework. These have been used as driving factors of design outcomes. Figure 5.47 illustrates all ten criteria have been established in the developed design designed.

The final design outcome (chapter 6) illustrates these ten criteria and use these as a measure of success.
Figure 5.47. Design framework criteria that have been satisfied by the design processes.
Figure 5.48. Exploded axonometric of the developed floor plans for Block A.
Figure 6.01. McLean Flats: original building on site
The final design has been assessed in terms of the ten criteria of the design framework. The design framework has been used as a guide to drive the design processes and measure the success of the design outcomes.

Each criterion has been established throughout design development and is indicated how this is achieved through design outcomes.

CHAPTER 7.0

Design Conclusions
Figure 7.02. Wellington City, the initial scope of this thesis research
7.1

CRITICAL REFLECTION

While architectural precedents are designing new builds for social housing, it is the occupant's needs and requirements that get lost in these economically focused developments. This thesis reassesses social housing, providing a positive prefabricated architectural response that embodies a sense of community and empowerment. This is an architectural solution that social housing tenants are in dire need of.

This thesis, by approaching social housing from an architectural and prefabrication perspective, makes a unique contribution to this area of research. The prefabrication methods utilised in this research project offers a collaborative approach to a construction system so as not to restrict and dominate the architecture. The development of the Servicebox enabled the flexibility and adaptability needed to create floor plan arrangements that are not restrictive. Further development could see this unit prototyped and marketed for industry use.

The outcome of this thesis is both an architectural building and a social tool; architecture developed to abolish social stigmas associated with social housing and to some extent prefabrication. The literature review outlined many conditions specific to the needs of occupants of social housing and for achieving positive atmospheric qualities desired in this type of housing. The architecture developed addresses these issues through a design framework, (figure 7.03), used to drive the design process, and as a tool to measure the success of the final design outcome. This thesis addresses the social stigmas associated with this context of housing, it presents
Figure 7.03. Ten criteria of the design framework fulfilled by the final design outcome
the differences in secure and high quality housing that achieves diverse atmospheric qualities, banishing stigmas and facilitates better communities and empowers occupants

When critiquing architectural precedents against the design framework that was developed, initial links showed that it was not possible to achieve low-cost prefabricated housing that satisfies each criterion. However, using this framework to drive the design processes and critique outcomes enabled the development of a final design that fulfils the criteria established in the design framework. It is the level of success achieved in satisfying these criteria that sets this project apart from current low-cost housing schemes. The methodologies employed, sketching, digital modelling, diagramming, planning, and programming through an iterative design-led process, has resulted in a housing development that meets, contributes and supports the complex needs of social housing occupants and communities.
7.2

SCOPE & LIMITATIONS

To stay within the scope of a one year design thesis, this research focused on establishing one example of a housing configuration on an inner city site that meets the research aims and objectives.

The scale, scope and timeframe of this research meant it was not possible to observe and engage with the tenants of current social housing located in Wellington City. Instead, experts in the field of low-income housing were invited to critique the project at design reviews and development meetings. Their support, in regard to the legitimacy and consideration of the project, strengthened the belief that the solutions developed in this thesis could be successful solutions, to the identified issues.

The scope of this research is contained to central Wellington, where social housing is predominately being pushed out to the suburbs. While this research is specifically designed for a site in central Wellington, there is potential for application of the design outcome to other cities as well as suburban areas.

This research scope focused on developing diverse atmospheric qualities to address the complex needs of social housing tenants. While this design has been tested in terms of its desirability against the design framework for its proposed occupants, in a theoretical sense, it has not been assessed by potential occupants or reviewed in monetary terms. For this design to accurately reflect the established design framework further, in-depth analysis would need to be carried out and tested with the potential occupants and primary stakeholders of social housing.
7.3

FUTURE DEVELOPMENTS

The knowledge and developmental systems presented in this thesis offers an opportunity for further research exploration. In particular, this proposal has addressed one specific site chosen for its challenging conditions, however, different sites and topographies creates their own set of constraints and opportunities. Testing on a range of sites would open a range of potential research possibilities into the manipulation of this hybrid prefabrication model and diversity of atmospheric conditions that are achievable for a positive living environment.

Beyond the scope of this thesis and as further opportunity for research the Servicebox offers interesting design potential. With further development and prototyping this module could be brought to an industry standard suited for social housing throughout New Zealand. In addition, further analysis and design experimentation to investigate the extent to which the design framework developed in this thesis could benefit the social housing sector could be undertaken. The design framework driving this design process was developed through relevant literature and used as a tool to critique case studies against and measure the success of the design outcomes. With further development, this framework as well as the architecture generated through this line of research can become a solution to New Zealand’s social housing issues that abolishes the social stigma’s attached providing a desired and diverse atmospheric quality needed to empower occupants.
